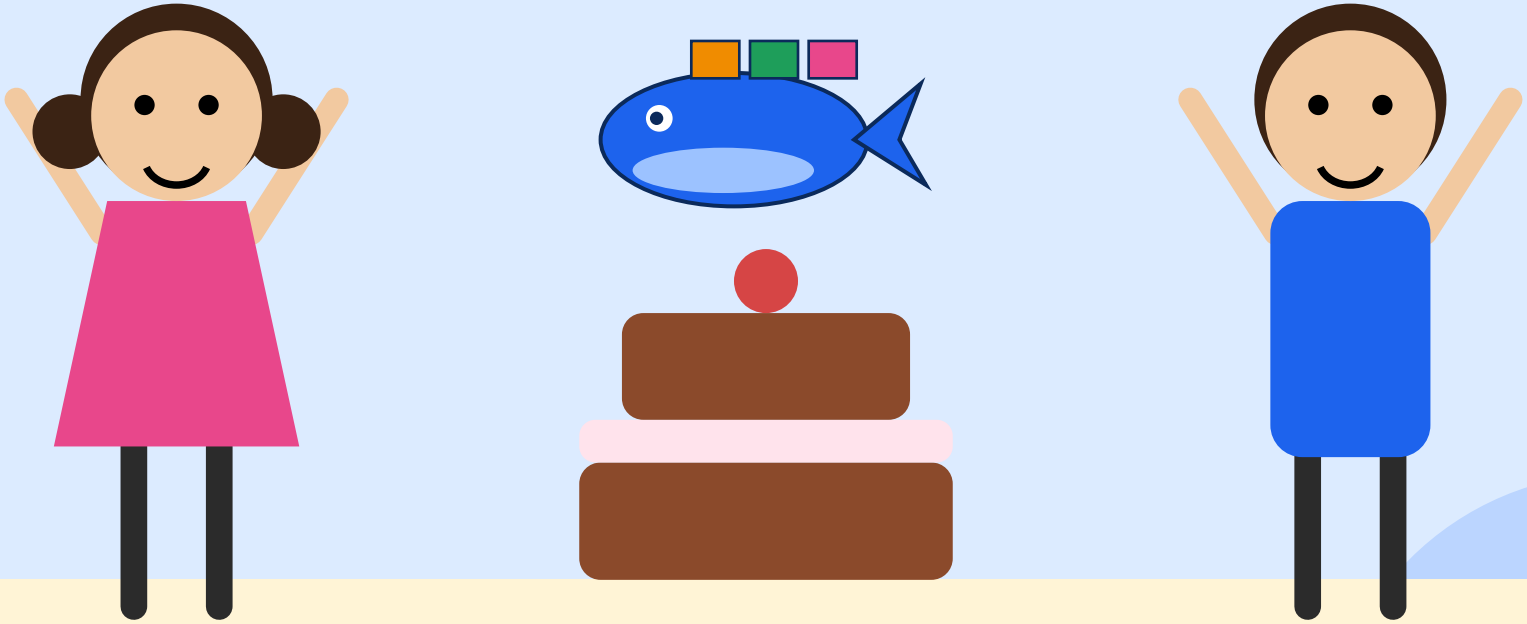
# Riya's Cake Shop

## and the Magic Box

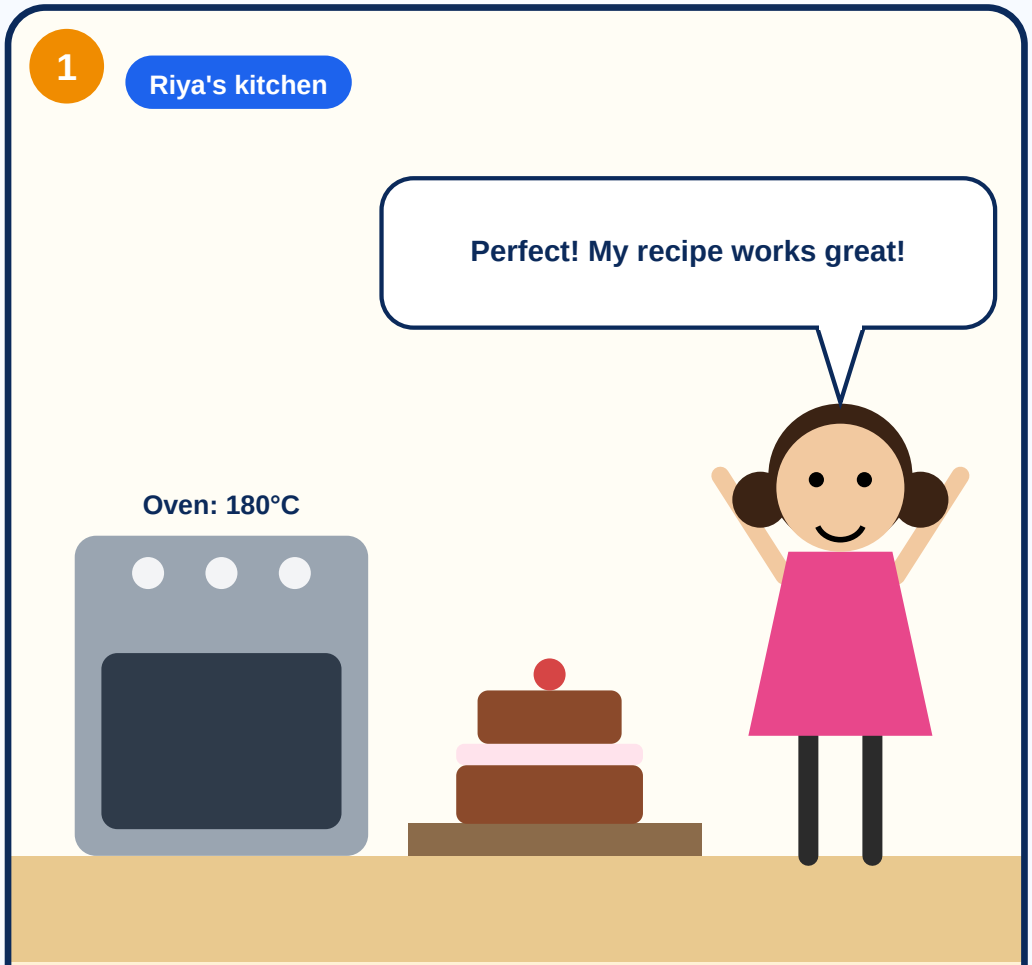
Docker explained as a story. No tech knowledge needed!

**Week 1 - Episode 1 - Story Edition**

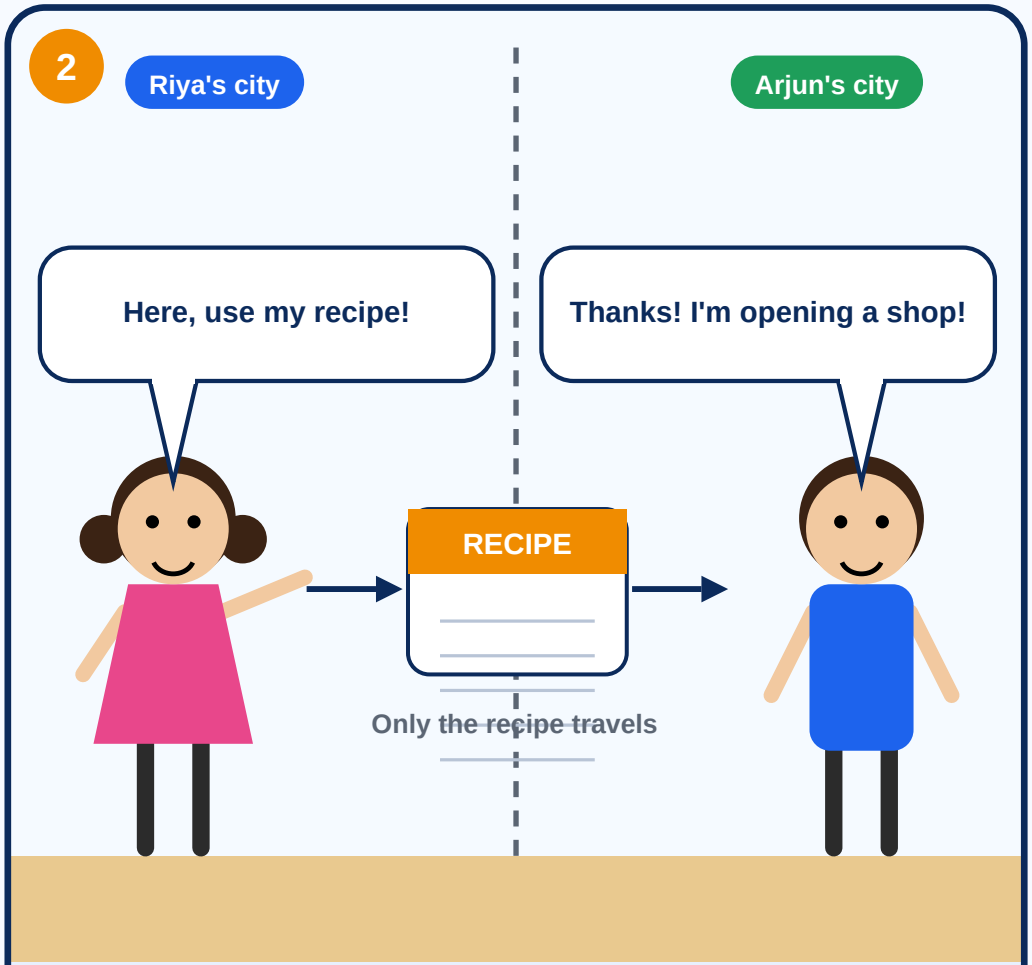


Meet Riya (the baker) and Arjun (the shop owner). Follow their cake to learn what Docker is.

# Part 1: The Perfect Cake



Riya bakes a perfect chocolate cake in her kitchen: her oven, her flour, her settings. TECH: a developer's app works great on their own laptop.



Riya shares just the recipe with her friend Arjun, who opens a shop in another city. TECH: code is sent to a test or production server.

# Part 2: The Problem

3

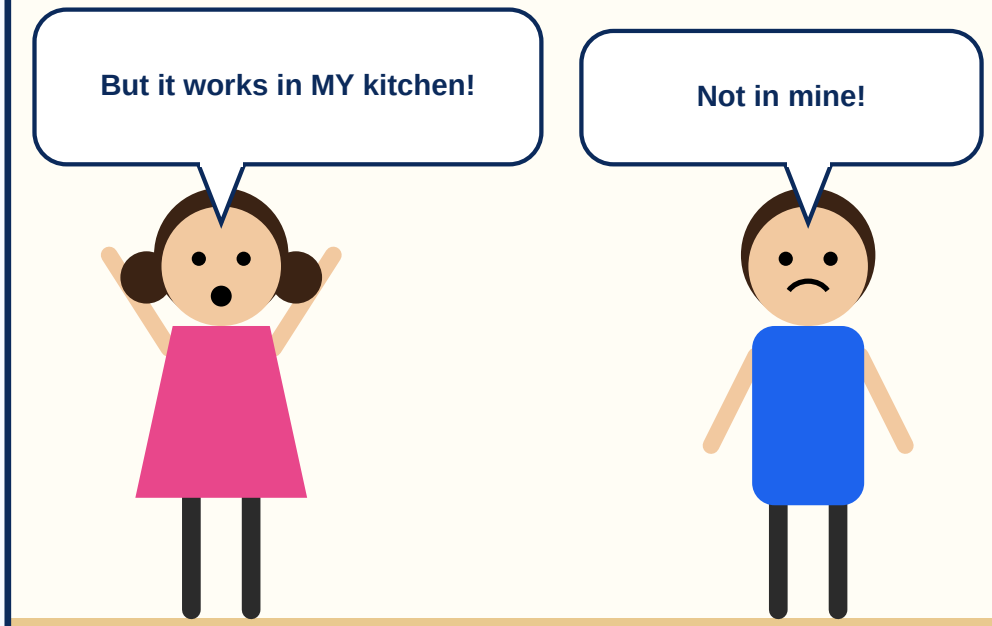
Arjun's shop kitchen

X Hotter oven | X Different flour | X No vanilla

Same recipe, different kitchen: hotter oven, different flour, missing vanilla. The cake is ruined! TECH: wrong Python version, missing library, different settings.

4

"It works on my machine!"



Riya: "But it works in MY kitchen!" This famous complaint wastes hours of every tech team's time. Docker was invented to end it.

# Part 3: The Magic Box Idea

5

Riya's idea: pack the cake recipe AND the flour, spices and oven settings into one sealed box. TECH: Docker packs the app plus everything it needs.

6

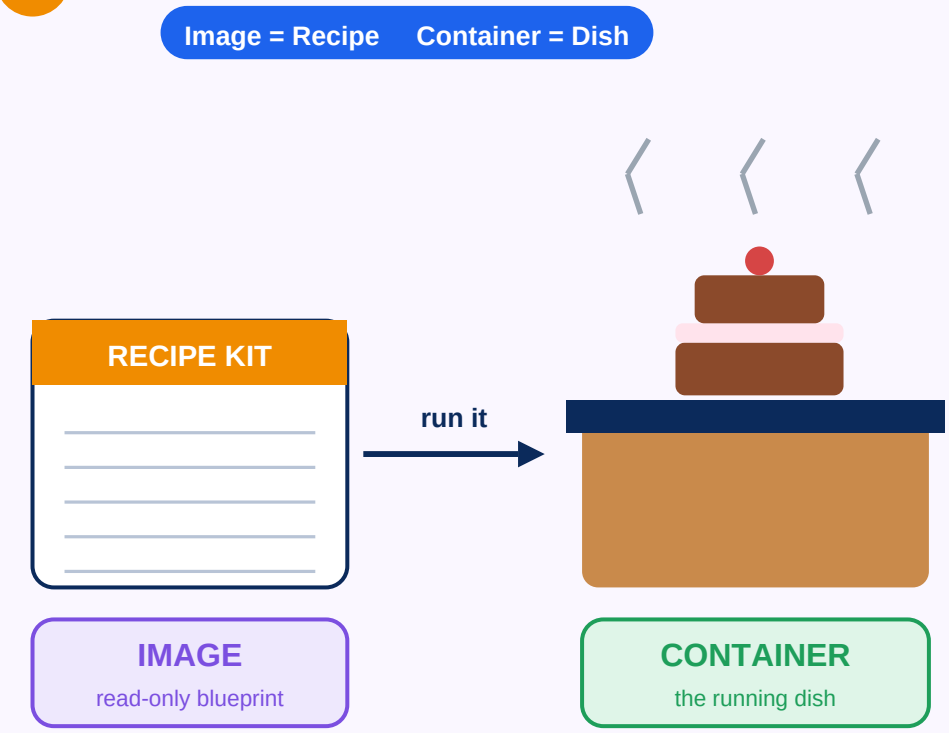


Image = the frozen recipe kit that never changes. Container = what you get when you open and run it. One kit, one running dish.

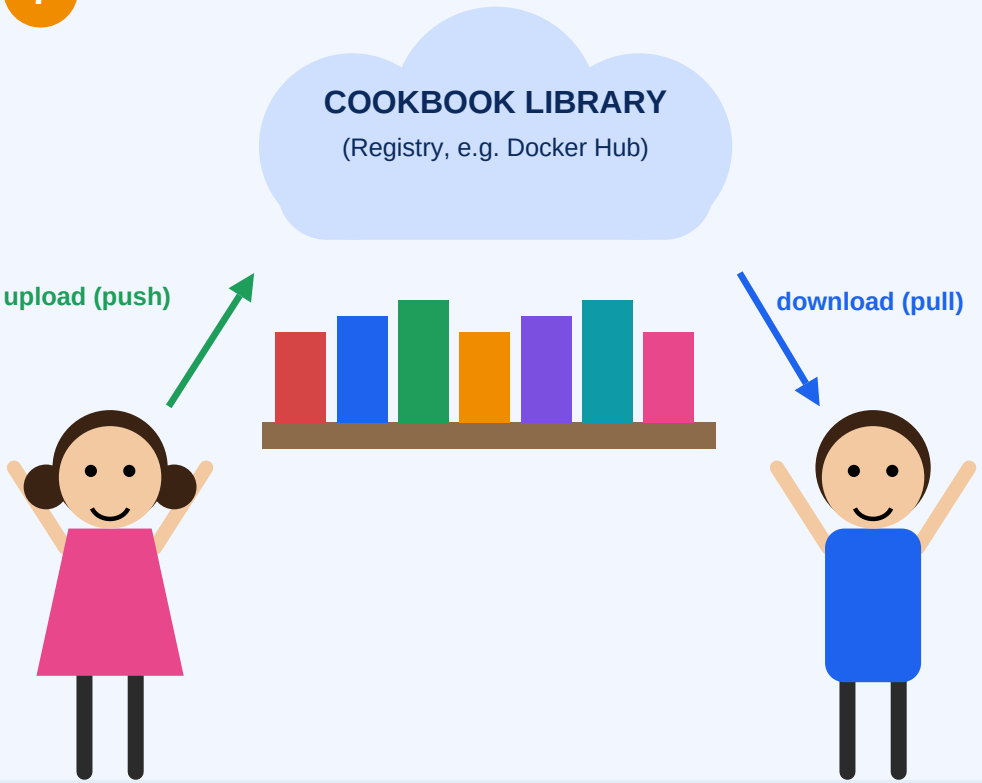
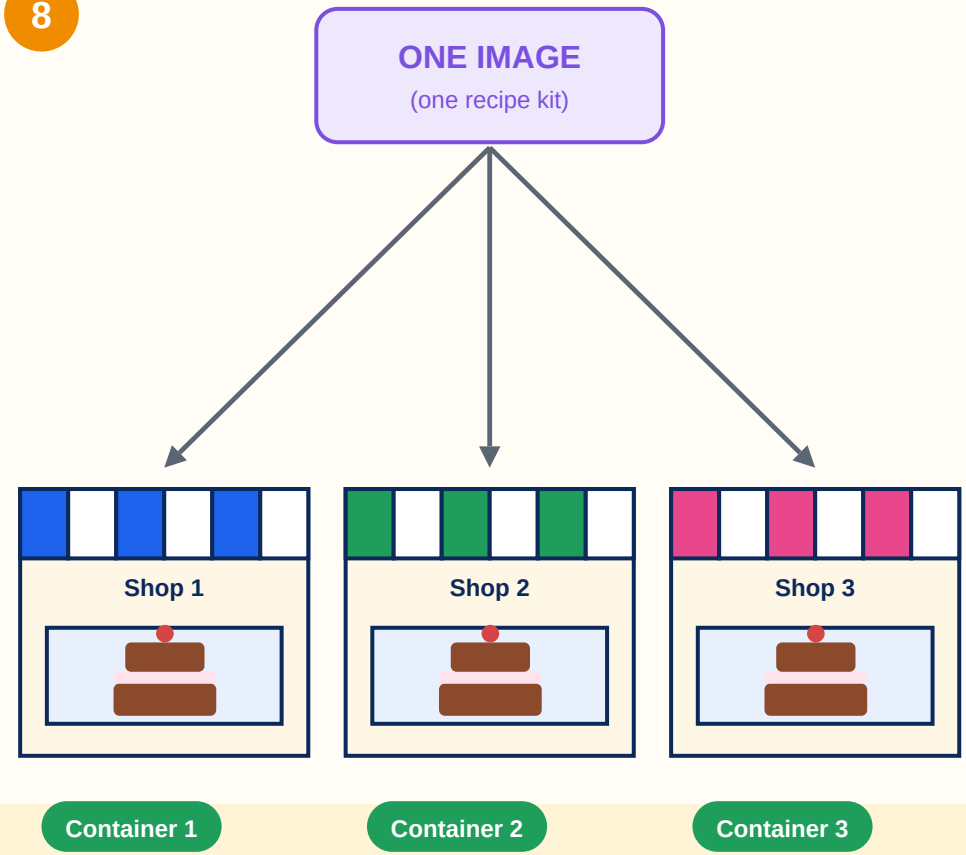
# Part 4: Sharing and Reusing

7



A registry is a cookbook library for images. Riya uploads her kit (push) and Arjun downloads it (pull). Docker Hub is the most popular one.

8

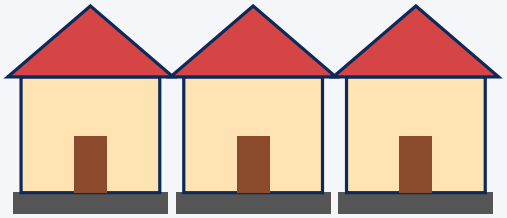


One image can start many containers. Three shops, three containers, the exact same cake every time. TECH: scale an app by starting more containers.

# Part 5: Why It's Light, and the Happy Ending

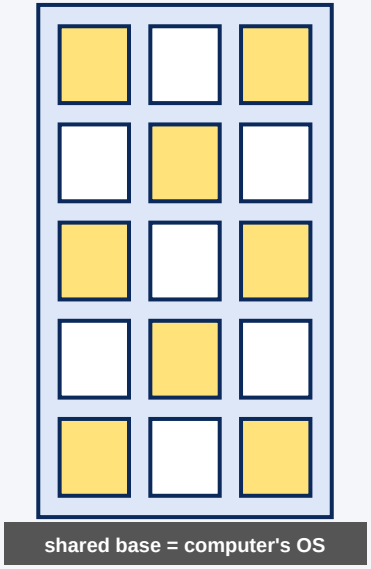
9

**Virtual Machines**



Each VM is like a separate house: own foundation, own plumbing. Heavy, slow, costly.

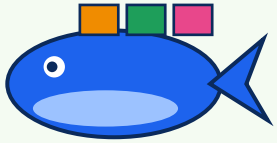
**Containers**



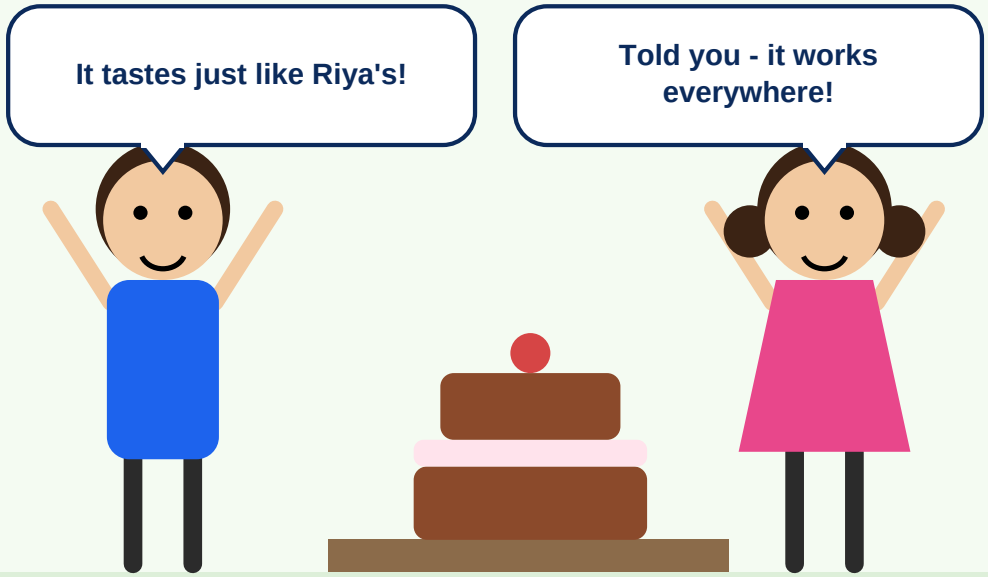
Containers are apartments in ONE building: light, quick, cheap.

A virtual machine carries a whole operating system, like building a house for each family. Containers share one OS, like apartments in one building.

10



Docker



Arjun opens the box and the cake tastes exactly like Riya's. Same box = same result on ANY computer that has Docker. No more excuses!

# Story-to-Tech Dictionary

| In the story | In real tech |
|---|---|
| **Riya's kitchen** | A developer's laptop |
| **Arjun's shop** | A test or production server |
| **Different oven and flour** | Different software versions and settings |
| **The recipe only** | Just the app's code |
| **Magic sealed box idea** | Docker |
| **Frozen recipe kit** | Image (read-only blueprint) |
| **Opened box, cake baking** | Container (running copy of an image) |
| **Cookbook library** | Registry (Docker Hub) |
| **Separate houses** | Virtual machines (heavy) |
| **Apartments in one building** | Containers (light) |

### Remember

- Docker packs an app with everything it needs.
- It runs the same on every computer with Docker.
- Image = recipe kit. Container = the dish.
- Registry = cookbook library.
- Containers are lighter than VMs.
- No more "works on my machine"!
